

# CS 340 Project Step 6 for My Kidney Nutrition Tracker Application

Project Group 70-Charles Cal and Deanna Denny

URL: <http://flip3.engr.oregonstate.edu:3331/>

(have to be connected to VPN)

## **Executive Summary**

In the beginning of our project we had more feedback and issues to resolve as we learned more about databases from the class and as we gained more knowledge and feedback too from our peers/grader. We determined and filtered what was applicable to add within our project. We even overcame odd glitches in Flask and the Flip servers that caused our database to time out constantly.

Throughout this project we were heavily influenced by peer reviews, instructor feedback, attendance in office hours seeking more advice, and collaboration within our group. Early on, feedback focused on database design. Based on instructor feedback we eliminated a 1:M relationship between Dialysis\_Forms and Patients, as this relationship was redundant with the 1:M relationship between Patients and Lab\_Results. To ensure we maintained naming consistency, we changed the names of all attributes tracking units to their singular form. Also for naming consistency, we renamed our "Food" table to "Foods." We identified that we needed to include both an ER diagram and a schema to convey both detailed and generalized models for our database. We achieved this by re-creating our ER diagram with a simplified model, focusing only on relationships between entities, primary, and foreign keys.

We then updated our schema based on normalization principles learned in the "Module 5: Normalization Steps" exploration. We learned from this module that our database was not normalized as we thought from online research we conducted previously so we eliminated further redundant data such as units for each lab value and food nutrient units.

We received several pieces of feedback that suggested expanding the scope of our database. We tried to implement these suggestions, but ultimately opted for a simpler model to practice the principles we learned in the class explorations.

We deployed our application on the flip servers using gunicorn and the class MySQL database. At this point, we struggled to troubleshoot an issue that was causing our database connection to timeout. Based on peer and ULA suggestions, we rectified this issue after identifying that it was ultimately caused by multiple database connections set up within each route. We refactored our code for readability and to add citations and improved our UI front-end appearance. We finished all the required CRUD operations and improved their functionality. We used the Lab Results relationships with Patients and with Dialysis\_Forms as our nullable relationships, and ensured our UI supported adding null values for each of these to the Lab\_Results table.

Overall, we took a considerable amount of time to reflect on the feedback that was given and implemented what was most applicable in the creation of our final project.

## **Project Outline and Database Outline:**

### **Overview**

Kidney disease impacts around 37 million people within the United States and is one of the leading causes of death. Health insurances pay an estimated \$87.2 billion to treat chronic kidney disease and around \$37.3 billion to treat those who have end-stage renal disease.<sup>[1]</sup> Around 81% of kidney disease patients own a cell phone that has the ability to connect to mobile applications.<sup>[2]</sup> More generations are tech savvy and becoming more reliant on telehealth/web development technologies. There are 786,000 patients with end-stage renal disease with appropriately 550,000 on dialysis within the United States.<sup>[3]</sup> We would anticipate that our application would start off with a goal of reaching 100,000 patients but a long-term goal of reaching the 81% of dialysis population with mobile phones that have application access.

The diet for individuals who have kidney disease is one of the most complicated diets to follow which include potentially restricting phosphorus, sodium, and potassium. There are currently more than 165,000 health-related and diet applications where only one-third of these actually focus on chronic diseases. Most of the current kidney-related applications information that is provided are not accurate or evidence-based. Many of them such as Kidney APPetite, Kidney Diet and Pocket Dietitian have been discontinued with newer operating systems.<sup>[4]</sup>

Our database driven website will provide a niche that is not currently being represented in today's market for dialysis. Especially bringing in renal dietitian skills paired with development; there is currently nothing that exists with this experience mixture but needs to in order to provide accurate and evidence-based information to those that struggle with their diet and require this information to be accessible to them. In this database, we will provide our Patient (on dialysis) with a tracking system for their Foods consumed which will allow the Patient to track specific nutritional content that is renal-focused to help them achieve their health goals/Lab Results that are within metric benchmarks. These Lab Results are influenced by what Foods the Patient decides to consume and impacted by the Dialysis Form they are on as well. This database will provide the Patient with the resources ultimately to achieve better outcomes while tracking certain attributes that influence their abilities to achieve these goals.

Outside the scope of this project, we would look at including additional details, such as prohibited foods for transplant patients, or a limited record of what drugs

patients may be taking. We also see this database as forming a structure that could be replicated to address other dietary-related health disorders.

## **Database Outline**

### **Entities & Attributes:**

**Patients:** Records the details of the patients. Focusing on patients with end-stage renal disease that are on dialysis.

- patient\_id: INT (11), auto\_increment, unique, not NULL, PK
- last\_name: VARCHAR(128), not NULL
- first\_name: VARCHAR(128), not NULL
- age: INT (11), not NULL
- gender: VARCHAR(20), default NULL
- height: INT(11), not NULL
- weight: INT(11), not NULL
- Using customary units for height and weight assumed to be reported as weight in pounds and height in inches.
- relationship: M:N relationship with Foods implemented with Patients\_patient\_id and Foods\_food\_id as a FK inside of Patients\_Foods. Along with a timestamp of patient\_food\_time DATETIME().
- relationship: 1:M relationship with Lab\_Results implemented with Patients\_patient\_id as a FK inside of Lab\_Results.

**Foods:** records the foods the patients consume focusing on minerals/calories that need to be watched in the renal diet. These main minerals include phosphorus, potassium, and sodium. Along with focusing on calories consumed too. Recommended units for potassium, sodium, and phosphorus are mg, and the recommended unit for calories is kcals. Amount is the number of grams in a serving size.

- food\_id: INT (10), auto\_increment, unique, not NULL, PK
- food\_name: VARCHAR(128), not NULL
- phosphorus\_content: INT(11), default NULL
- sodium\_content: INT(11), default NULL
- calories: INT(11), default NULL
- potassium\_content: INT(11), default NULL
- amount: INT(11), default NULL

- Using Metric system's standardized units: potassium/phosphorus/sodium nutrient content would be in mg, and calories would be in kcals. Food portions/amounts would be reported in grams.
- relationship: M:N relationship with Patients implemented with Foods\_food\_id and Patients\_patient\_id as a FK inside of Patients\_Foods. Along with a timestamp of patient\_food\_time DATETIME().

Lab\_Results: records the lab results of the kidney patients that are nutritionally relevant such as phosphorus, potassium and sodium levels. It is also important to monitor adequacy or also known as Kt/v which is a metric that shows how well the patient is dialyzing which is heavily influenced by the type of dialysis they are on since different forms of dialysis have different adequacy metrics to meet. Recommended units for phosphorus is mg/dL, and for sodium and potassium is mEq/L.

- lab\_id: INT(11), auto\_increment, unique, not NULL, PK
- phosphorus\_lab: FLOAT
- potassium\_lab: FLOAT, default NULL
- sodium\_lab: INT(11), default NULL
- dialysis\_adequacy\_lab: FLOAT, default NULL
- lab\_results\_time: DATETIME(), default NULL
- Utilizes the Conventional Unit system for laboratory values which is adapting the standardized units used within the United States for these lab values: sodium mEq/L, potassium mEq/L, and phosphorus mg/dL.
- relationship: M:1 relationship with Patients implemented with Patients\_patient\_id as a FK inside of Lab\_Results. This is a nullable relationship, as this entry is optional.
- relationship: M:1 relationship with Dialysis\_Forms implemented with Dialysis\_Forms\_dialysis\_id as a FK inside of Lab Results. This is a nullable relationship, as this entry is optional.

Dialysis\_Forms: records the type of dialysis the kidney patient is on; common types of dialysis include in-center, home-hemo, and peritoneal dialysis. The form of dialysis can affect the desired lab results, and different forms of dialysis have different desired adequacy metrics.

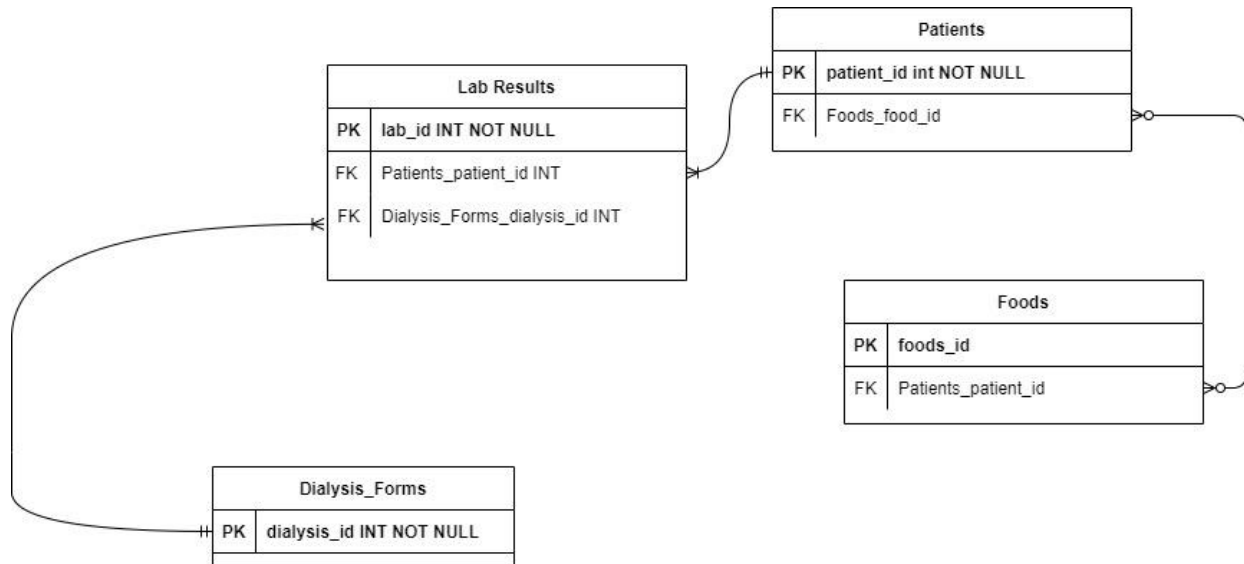

- dialysis\_id: INT(10), auto\_increment, unique, not NULL, PK
- name: VARCHAR(128), not NULL
- location\_type: VARCHAR(128), not NULL
- adequacy\_standard: FLOAT, not NULL
- relationship: 1:M relationship with Lab\_Results implemented with Dialysis\_Forms\_dialysis\_id as a FK inside of Lab\_Results.

### Intersection Table:

Patients\_Food: Intersection table between Patients and Foods. This connects the patients to food that they have eaten, and adds a time characteristic for when the patient ate the food.

- food\_patient\_id: INT, PK
- Foods\_food\_id: INT (10), FK ON DELETE CASCADE
- Patients\_patient\_id: INT (11), FK ON DELETE CASCADE
- patient\_food\_time: DATETIME(), not NULL

## Schema:

To normalize our schema we first created tables that we compiled that would fit our report structure in excel. We eliminated applicable redundant data to make it a first normal form (1NF). We then identified the primary keys within our tables and dependencies. Then we eliminated partial dependencies so that it fits the second normal form (2NF). We reassigned/omitted applicable dependent attributes. We then ensured it was in the third normal form (3NF) by making sure we resolved all transitive dependencies. We followed the normalization steps that were in our module 5 exploration on normalization steps.<sup>1</sup>

Part of these normalization steps, we decided to utilize the Conventional Unit system for laboratory values which is adapting the standardized units used within the United States for these lab values: sodium mEq/L, potassium mEq/L, and phosphorus mg/dL.<sup>2</sup> Since they are based on the Conventional Unit system there is no need to explicitly label each of them in the database on the Lab\_Results table. For food measurements we used the Metric system's standardized units: potassium/phosphorus/sodium nutrient content would be in mg, and calories would be in kcals within the Foods table. Food portions/amounts would be reported in grams on the Foods table.<sup>3</sup> We are using Customary units for weight and height in the Patients table which reports weight as pounds and height in inches.<sup>4</sup> We decided since we are using the typical standards that are reported within the dialysis community and in the United States that we decided to leave that information out of the database we designed.

By standardizing units with commonly used unit systems within the United States we were able to successfully decrease the amount of duplication that comes from our previous database and more so fitting the expected guidelines within a 3NF. It also eliminated the partial dependencies as well. See on next page the detailed schema model.

## Schema Model:

### **Example Data:**

All sample data is based on fictional patients. Lab standards, dialysis forms, and food data are referenced from sources below. Refer as well to our SQL file containing our Data Definition Queries (DDL) for more information.

### **Patients Table:**

<b>Patients</b>						
patient_id	last_name	first_name	age	gender	height	weight
1	Smith	Arlene	55	F	64	145
2	Rogers	Christopher	63	M	72	180
3	Harrison	Kayla	68	F	65	125
4	Jackson	Henry	74	M	75	200
5	Wonders	Brenda	91	F	60	92

\*Patient information is fictional\*

patient\_id = auto generating

Height in inches and weight in lbs considered Customary standardized units.

### **Lab\_Results Table:<sup>5</sup>**

<b>Lab_Results</b>							
lab_id	phosphorus_lab	potassium_lab	sodium_lab	dialysis adequacy_lab	lab_results_time	Patients_patient_id	Dialysis_Forms_dialysis_id
1	3.5	3.4	135	1.2	2022-05-07 23:22:05	3	1
2	5.5	3	142	1.7	2022-05-08 18:36:10	2	2
3	6.5	2.8	146	1.1	2022-05-01 20:20:06	4	1

---

<sup>5</sup> *Understanding your lab work*. DaVita. (n.d.). Retrieved April 25, 2022, from <https://www.davita.com/education/kidney-disease/symptoms/understanding-your-lab-work>

4	10.5	6.6	144	0.6	2022-05-07 18:01:55	5	1
5	7.2	4.5	134	2.2	2022-05-11 10:19:25	1	2

lab\_id, Patients\_patient\_id, Dialysis\_Forms\_dialysis\_id = auto generating  
Using Conventional standardized units for lab values: potassium and sodium measured in mEq/L and phosphorus in mg/dL. Adequacy is measured as a benchmark metric with hemodialysis achieving 1.2 and peritoneal dialysis is achieving 1.7.

### Dialysis\_Forms Table:<sup>6 7 8</sup>

		Dialysis_Forms	
dialysis_id	name	location_type	adequacy_standard
1	hemodialysis FMC	incenter	1.2
2	peritoneal Baxter	home	1.7

### Dialysis\_id = auto generating

Adequacy is measured as a benchmark metric with hemodialysis patients achieving 1.2 and peritoneal dialysis 1.7.
